Abstract

Powdery mildews are important obligate biotrophic ectoparasites that cause severe damage to various plant species in Southeast Asia. So far, 14 genera and 96 species of powdery mildew have been reported in Southeast Asia, with Thailand having the most number of recorded species. Of the 14 genera reported, *Oidium* sp. had the most recorded host, including several important species of vegetables, fruits, vines, herbs, field crops, ornamentals, and tree species. This paper briefly reviews the knowledge of powdery mildew disease in Southeast Asia, focusing on the pathogens' host range, impact, and some sources of resistance to powdery mildew.

Introduction

Since the origin of powdery mildew in the Late Cretaceous period and ancestral powdery mildew were first unearthed on broad-leaved deciduous trees in the high latitudes of the Northern Hemisphere, that continued further speciation while spreading southward in the Paleogene and Neogene periods^[1], numerous reports have been recorded globally. As a result, comprehensive studies on elucidating powdery mildew disease were established. Powdery mildews are obligate biotrophic ectoparasites classified in *Leotiomycetes* (with primitive cup-fungi), the order *Erysiphales*, and the family *Erysiphaceae*. This includes 26 genera, > 900 species presently known worldwide^[2,3]. Powdery mildews are generally white and dusty in the conidial state. They live epiphytically, coat, exclusively feed on living epidermal cells, and fulfill their (a)sexual life cycle on leaf and small stem surfaces. They primarily attack young shoots, leaves, and inflorescences. As a result, the fruit set is reduced, and those that reach maturity are small, crunched, and cracked. The plant becomes stunted or chlorotic and has severe defoliation. This disease can spread rapidly and is prevalent in high humidity but does not require moist conditions to germinate, grow, establish, and infect^[4–6], and they usually thrive well even under warm and dry conditions.

The intensive and extensive cultivation of crops and other plant species has resulted in large-scale perpetuation, build-up, and dissemination of powdery mildews on plant species in Southeast Asia (SEA) and worldwide. In addition, Southeast Asia generally has warm, humid, and cooler temperatures in highland areas, which is favorable for powdery mildew disease. This review provides a brief synthesis of the current understanding of powdery mildew disease in Southeast Asia, emphasizing its reported powdery mildew species, host range, impact, and sources of resistance. Moreover, research opportunities would

contribute to a better understanding of the powdery mildew pathogen.

Powdery mildew species in SEA and their host range

Of the 26 currently accepted genera^[3,7,8] and > 900 species^[2] of the *Erysiphaceae* or powdery mildews, so far 14 genera (*Blumeria*, *Brasiliomyces*, *Cystotheca*, *Erysiphe*, *Fibroidium*, *Golovinomyces*, *Leveillula*, *Microidium*, *Odiopsis*, *Oidium*, *Ovulariopsis*, *Phyllactinia*, *Podosphaera*, *Pseudoidium*,) and 96 species (based on currently accepted species)^[9,10] were reported and listed from Southeast Asia (Table 1). The genus *Erysiphe* had the most number of species (25) reported. In terms of frequency of reports, *Oidium* sp. had the greatest number of host reports with occurrences recorded in Thailand, Brunei Darussalam, Myanmar, Cambodia, Indonesia, Laos, Malaysia, Philippines, Singapore, and Vietnam (Table 1). Nevertheless, some of these records were only up to the genus level. Hence, future sampling of powdery mildews would aid in verifying the species of *Oidium* infecting various plants in SEA.

Powdery mildew has been reported to host up to 9,838 plant species worldwide, all of which are angiosperms (flowering plants), including several economically important plants, and not gymnosperms, ferns (pteridophytes)^[7] or lower plants such as mosses and liverworts (bryophytes)^[11]. Thus, powdery mildew is considered one of the most important plant pathogens. Economically significant hosts in SEA includes vegetables, fruits, vines, herbs, field crops, ornamentals, and tree species. Most genera and species of powdery mildew disease are explicit to plants of a single genus. An example of this is *Blumeria* infecting only grasses (*Poaceae*). Thus far in SEA, Thailand has the most recorded powdery mildew hosts in a generally tropical, warm, and humid climate and practices intensive

agriculture, which makes them favorable for the proliferation of powdery mildew conidia. However, most of the host plants in the SEA are herbaceous species. This difference undoubtedly reflects the growth habit of the powdery mildew fungus, which is limited mainly to leaves and succulent shoots and stems.

Southeast Asian countries have a relatively low level of exploration, perhaps due to the limited number of experts or mycologists studying powdery mildews relative to Eastern Asia, Europe, and the rest of the world. Moreover, surveys and reports of powdery mildew in Southeast Asia have been sparse in recent years, which should contribute to and be updated to understand this ubiquitous plant pathogen better. Also, in subtropics and tropics, the powdery mildew's sexual reproductive stage (teleomorph), essential for accurate species identification, is largely absent^[12].

Impact

Diseases constitute a significant factor in diminishing yield and productivity in Southeast Asia, as they do elsewhere. Compared to other fungal diseases, powdery mildew causes less debilitating losses due to the lack of systemic and root infections and minimal host death^[101]. However, with the impact of climate change — the increased CO₂ emissions and rising temperatures in Southeast Asia (Myanmar, Philippines, Vietnam, and Thailand being among the most affected in the world by climate change^[102], powdery mildew disease may continuously aggravate in the future^[103–108] through increased colony establishment^[109] and effect in plant host's physiology and susceptible openings such as stomata^[110], resulting in a higher risk of infection. Powdery mildew disease may cause a disease outbreak which brings plant growth reduction, premature defoliation, and reduction in fruit quality and yield, especially of economically important crops resulting in significant economic loss if not managed in the early stages since fungal growth covers entire photosynthetic green areas of the plant hindering food manufacturing mechanism of host plants^[101].

Some recorded powdery mildew impacts in SEA are from legumes and important tree species. Yield reduction of 21%^[111] up to 58%^[112] in the Philippines, 50% in Thailand^[113], and 20%–40% in Southeast Asia^[41,114,115] have been recorded in mungbean that can lead to complete plant loss during seedling or early plant stage^[116]. A decline in soybean seed quantity, weight, physical quality, and germination of 50%–52%^[117] and a yield reduction of 10%–90% was recorded in Indonesia^[118]. In Indonesia, powdery mildew disease of rubber trees also posted a reduction in rubber latex yields by up to 45%, including damage to young rubber leaves, buds, inflorescences, and other immature tissues^[119,120]. Powdery mildew infection of 90%–100% of *Acacia auriculiformis* seedlings was recorded in Thailand, where about 75% of the seedlings were wiped out^[121]. Known tree hosts of powdery mildew may overcome the disease as it matures, as observed on > 2-year-old trees^[122].

Sources of resistance

Host plant resistance has been widely used in crop breeding to develop powdery mildew disease-resistant cultivars for avoiding or minimizing yield losses due to disease infestation. Some sources of resistance against powdery mildew have been identified in SEA (Table 2). The resistant genotypes listed range from highly resistant (HR) to moderately resistant (MR). These sources can be incorporated through conventional and biotechnological approaches to breeding powdery mildew-resistant cultivars.

Though these genotypes are reported to have powdery mildew resistance (high to moderate), races or shifts in virulence of the population occur since some of the resistance reported from the past years weakened or were not resistant anymore. Besides the possibility of race, other factors like inoculum density and environments can also influence the resistance or susceptibility of plant genotypes to powdery mildew^[123]. Nevertheless, a more stable resistance may be established using a combination of quantitative and major

genes in resistance breeding. The former serves as a buffer to the resistant cultivar, therefore supporting extending the lifespan of a resistant cultivar^[124].

Conclusions and research prospects

Many plant species in Southeast Asia are affected by powdery mildew dispersed to and from different parts of the world. It threatens various economically important vegetables, fruits, vines, herbs, field crops, ornamentals, and tree species in Southeast Asia and worldwide. A comprehensive survey of powdery mildews in these localities may be warranted to verify and update the existing genera and species and their hosts in Southeast Asia and clarify the biodiversity and evolution of this important plant pathogenic fungal group. It is also crucial to study the effects of climate change on the powdery mildew disease-host plant pathosystem, which may contribute to the exacerbation of the disease. Climate changes could alter virulence under cultivation and in natural habitats. Hence understanding how these abiotic factors and their interactions affect virulence has vital implications. It is also imperative to formulate cost-effective integrated disease management, i.e., cultural, chemical, biological, and host resistance to powdery mildew management strategies at each level, considering prevailing environmental conditions under several plant species.

Moreover, sources of powdery mildew resistance listed in Southeast Asia should also be described appropriately whether resistance in these genotypes is race-specific, based on a form of slow mildewing resistance, or non-host resistance, because studies show that race-nonspecific resistance to powdery mildew provides more durable disease resistance^[135]. Furthermore, the mechanism of non-host resistance against powdery mildew of various plant species should also be exploited, which is considered more durable and robust resistance^[101].

Conflict of interest

The authors declare that they have no conflict of interest.
